Cell Viability measures how long cells will stay alive after being cultured, that is, how long they are viable in a given experimental condition. In this project, cells were subjected to a -70°C freezer and different concentrations of glycerol as a cryoprotectant. Two organisms were tested in this experiment: *Schizochytrium* spp. and *E. coli*. Vial lots of each organism were made and placed in a -70°C freezer. After allotted times, vials with concentrations of 10% glycerol, 15% glycerol, and 20% glycerol added to the broth were tested by aerobic plate counts to see the viability of the cells. The *Schizochytrium* spp. vials were tested by a Cellometer® cell counter as well. The preliminary results seem to show that this experiment is a good and useful model for studying viability in these strains. Ultimately, this experiment will be run for two years in order to determine viability over time.
