Certain types of the human papilloma virus (HPV) have been implicated as the causative agent of cervical cancer. Cervical cancer is the second most common cancer among women worldwide and the third leading cancer related deaths in women. The clinical test commonly known as the Pap-smear can help detect infection, but is not widely available in lesser developed countries. The goal of this study is to use Bovine Papilloma Virus (BPV) to mimic HPV in the same procedure used for the previous study. That study showed that E5 and E7 mRNA levels were unequal due to the integration of HPV into the human genome. The goal of the present study is show the equivalence of E5 and E7 mRNAs in a non-integrated genome, in essence a positive control experiment for the previous study. The results of this study were largely inconclusive although the findings suggest the expected lack of integration. Further work is needed to develop an efficient primer to conclude this study.
