The Cuenca-Molleturo-Naranjal highway was recently constructed through the páramo region of the Cajas National Park in the Ecuadorian Andes. The impacts of this highway on the park avifauna- including many endemic and endangered species- are unknown. The purpose of this study was to determine how the highway may have influenced the distribution of male and female Plumbeous Sierra-Finches, one of the most common finch species in the park. Using point transect counts in October, 2011 we observed both sexes (N = 88 sightings) at 18 park locations. There was an equal sex ratio in transects near the highway (< 1 km), while zones farther from the highway (>1 km) had a significantly greater proportion of males. These results suggest that the preferred breeding territories were closer to the highway, which may provide greater foraging opportunities.
